

CAUTION

Lithium batteries can be extremely dangerous, if not handled and cared for properly. This design does not include any form of current limiting circuit, like a fuse. So, care must be taken to ensure that the wiring guidelines are followed accurately, that checks are made for short-circuits, and that battery polarities are marked, and they are inserted the correct way round. Failure to do so, could result in an explosive fire.

Charging Practices: Always remove batteries from your project to charge them. Use a charger, designed for the battery used, and from a trusted supplier. Choose a flat, non-flammable surface to charge on, away from flammable materials. Never leave unattended when charging. Don't charge overnight. Monitor charging to ensure charge characteristics are as expected. Only pair batteries with similar characteristics. Do not overcharge, or leave charging for prolonged periods. This increases the risk of damage and fire.

Battery care & maintenance: Stop using a battery if it is swollen, damaged, dented or leaking. Never charge a damaged battery. Never allow a Lithium battery to discharge below 3.2 volts, as cell damage will occur. Avoid extreme temperatures. Do not charge or store batteries in very hot or cold environments. Don't cover batteries whilst charging, as this can trap heat, causing overheating.

In case of fire: Get out and stay out. If a fire starts, leave immediately, and call the fire brigade. For low voltage Lithium batteries, water is a safe extinguisher.

Built-in Monitoring: Most of my project designs include code, and circuitry, to monitor battery voltage, whilst in use. This code then seeks to alert the operator, when the battery has reached a critical low voltage, before shutting down power consuming circuitry; including the micro. Time should therefore be spent on calibrating this feature, as a precaution, for good battery management and maintenance.

Carefully dispose of batteries that damaged, or discharged below their critical voltage.

Hand Tools:

Recommended:

- Fine Nosed Pliers
- Side Cutters
- 1.5 mm Drill
- 2.0 mm Drill
- 4.0 mm Drill
- Needle Files
- Screwdrivers
- Craft Knife

Note: Not all items are shown here.

Tools & Materials:

Temperature controlled iron

Solder flux

Resin cored solder

Hot melt glue gun {optional}

2-part epoxy resin glue

Screw drivers

Tweezers

Wire wrapping tool

Wire wrapping wire 30 AWG

24 AWG stranded wire (red, black & yellow)

Multimeter

Special Tools

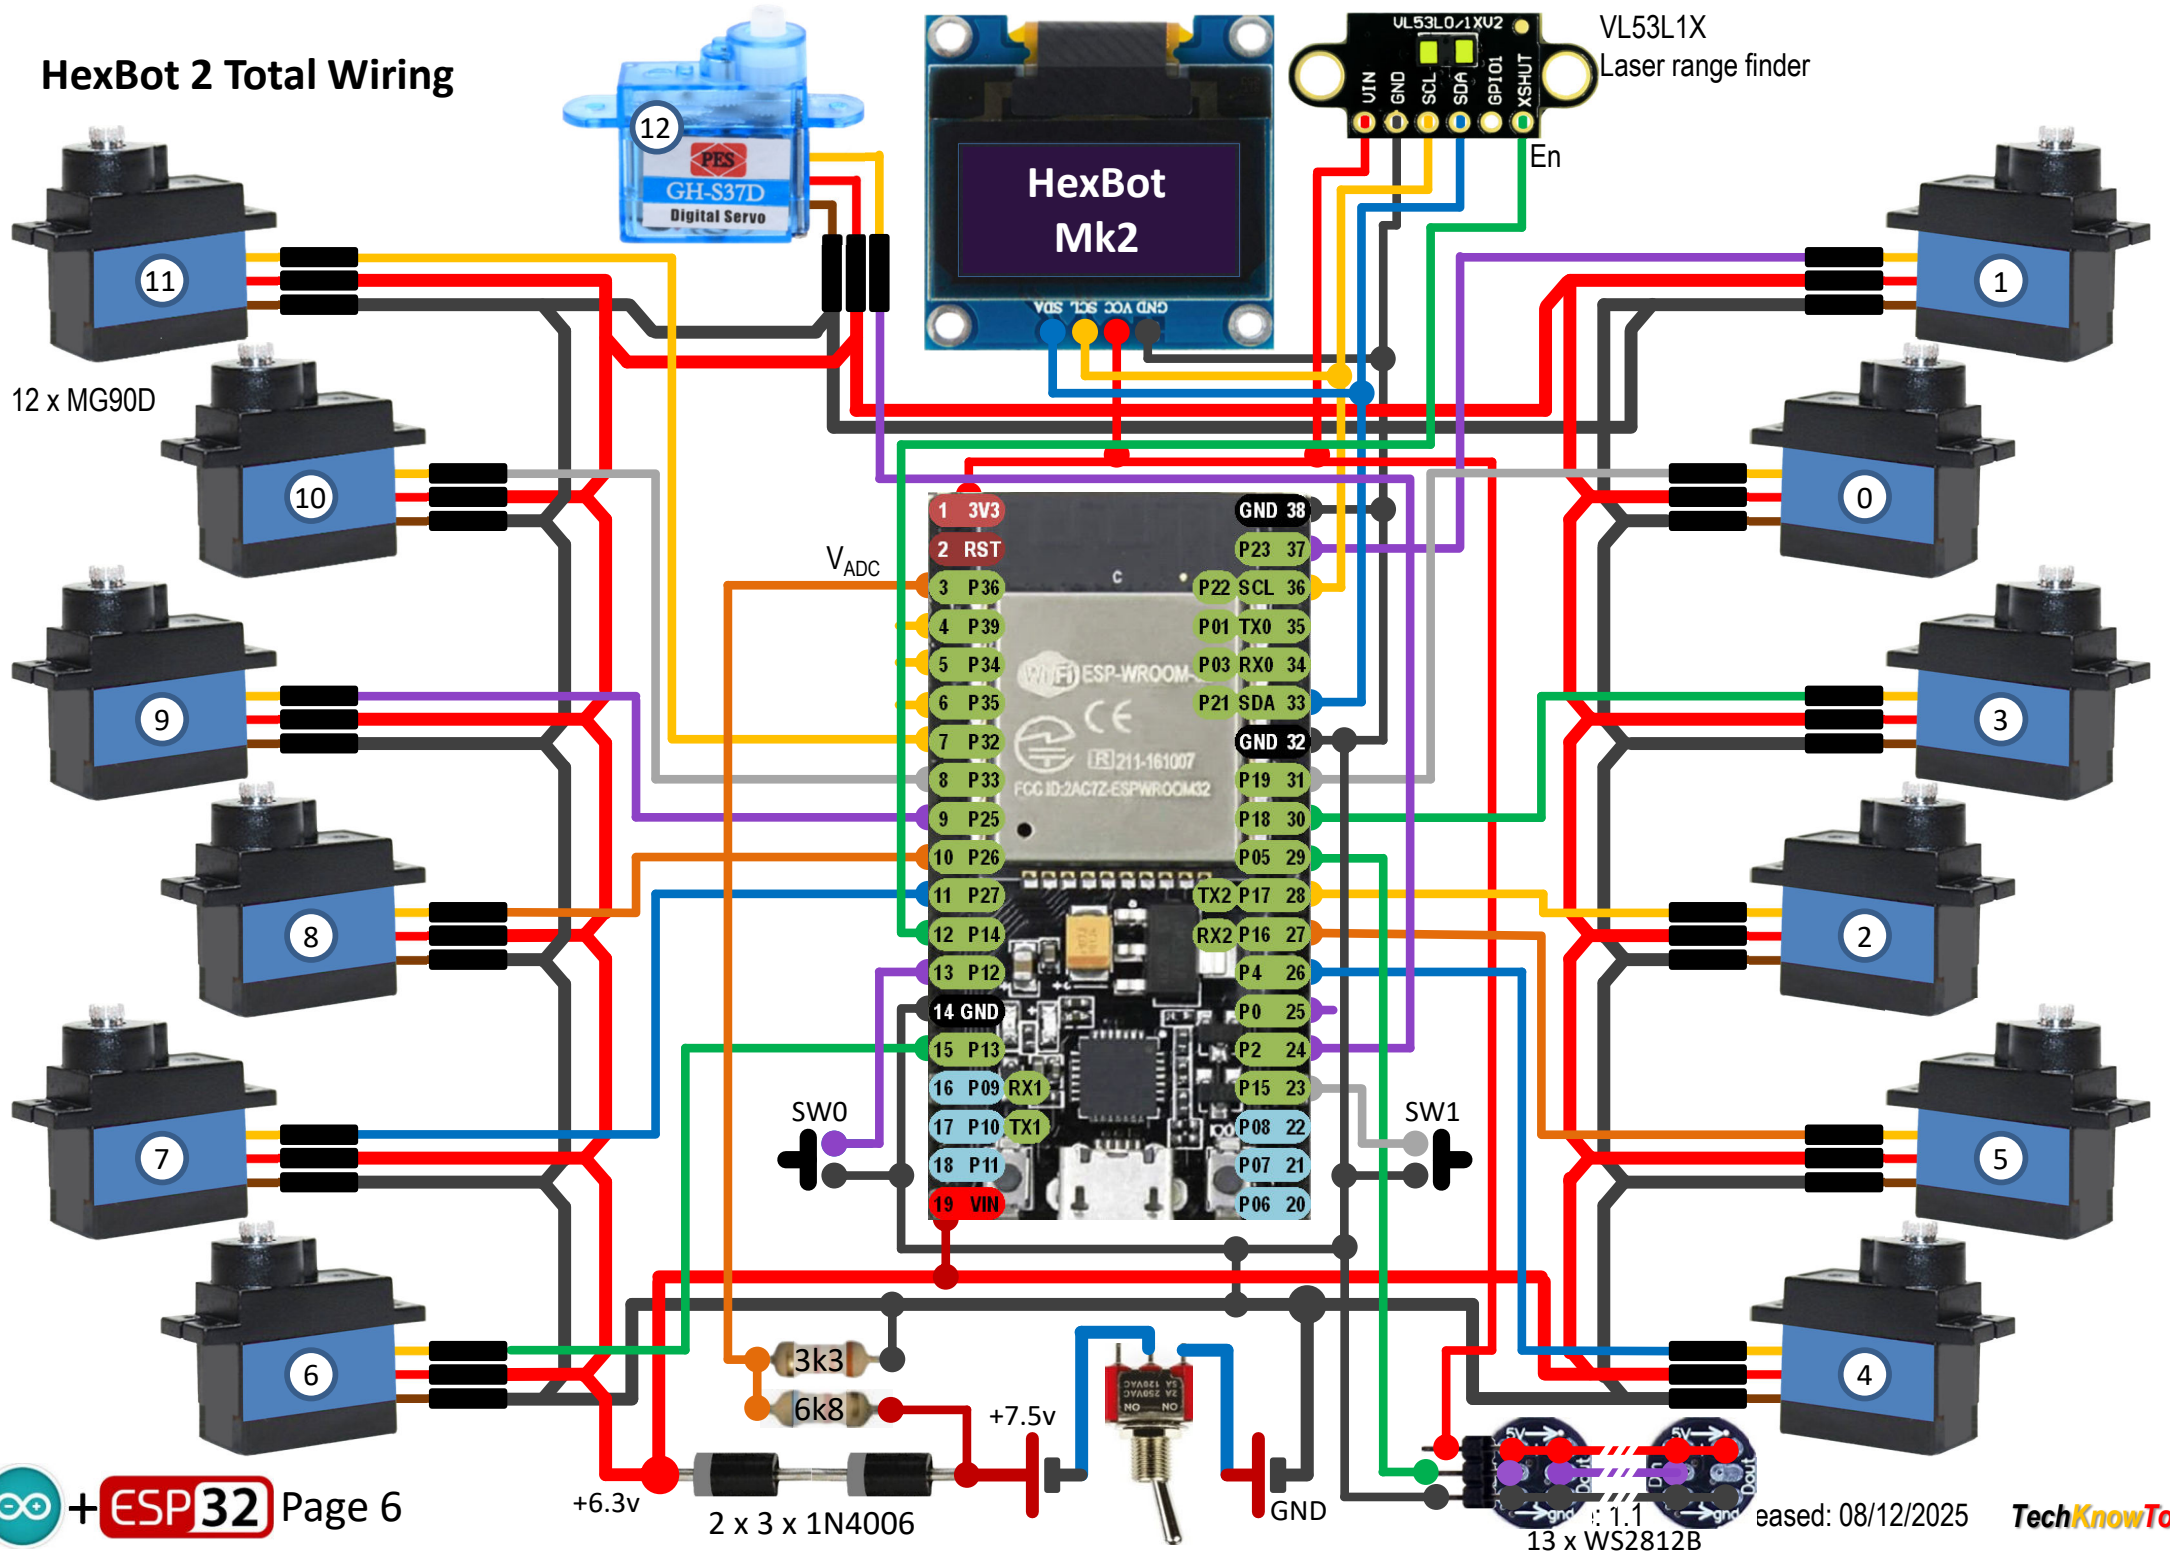

Hot air gun for heat shrink sleeving

Ratchet crimping tool + 2.54mm female connectors

Watch videos on the internet to learn how to best use this tool, before attempting to shorten the servo leads.

HexBot 2 Total Wiring

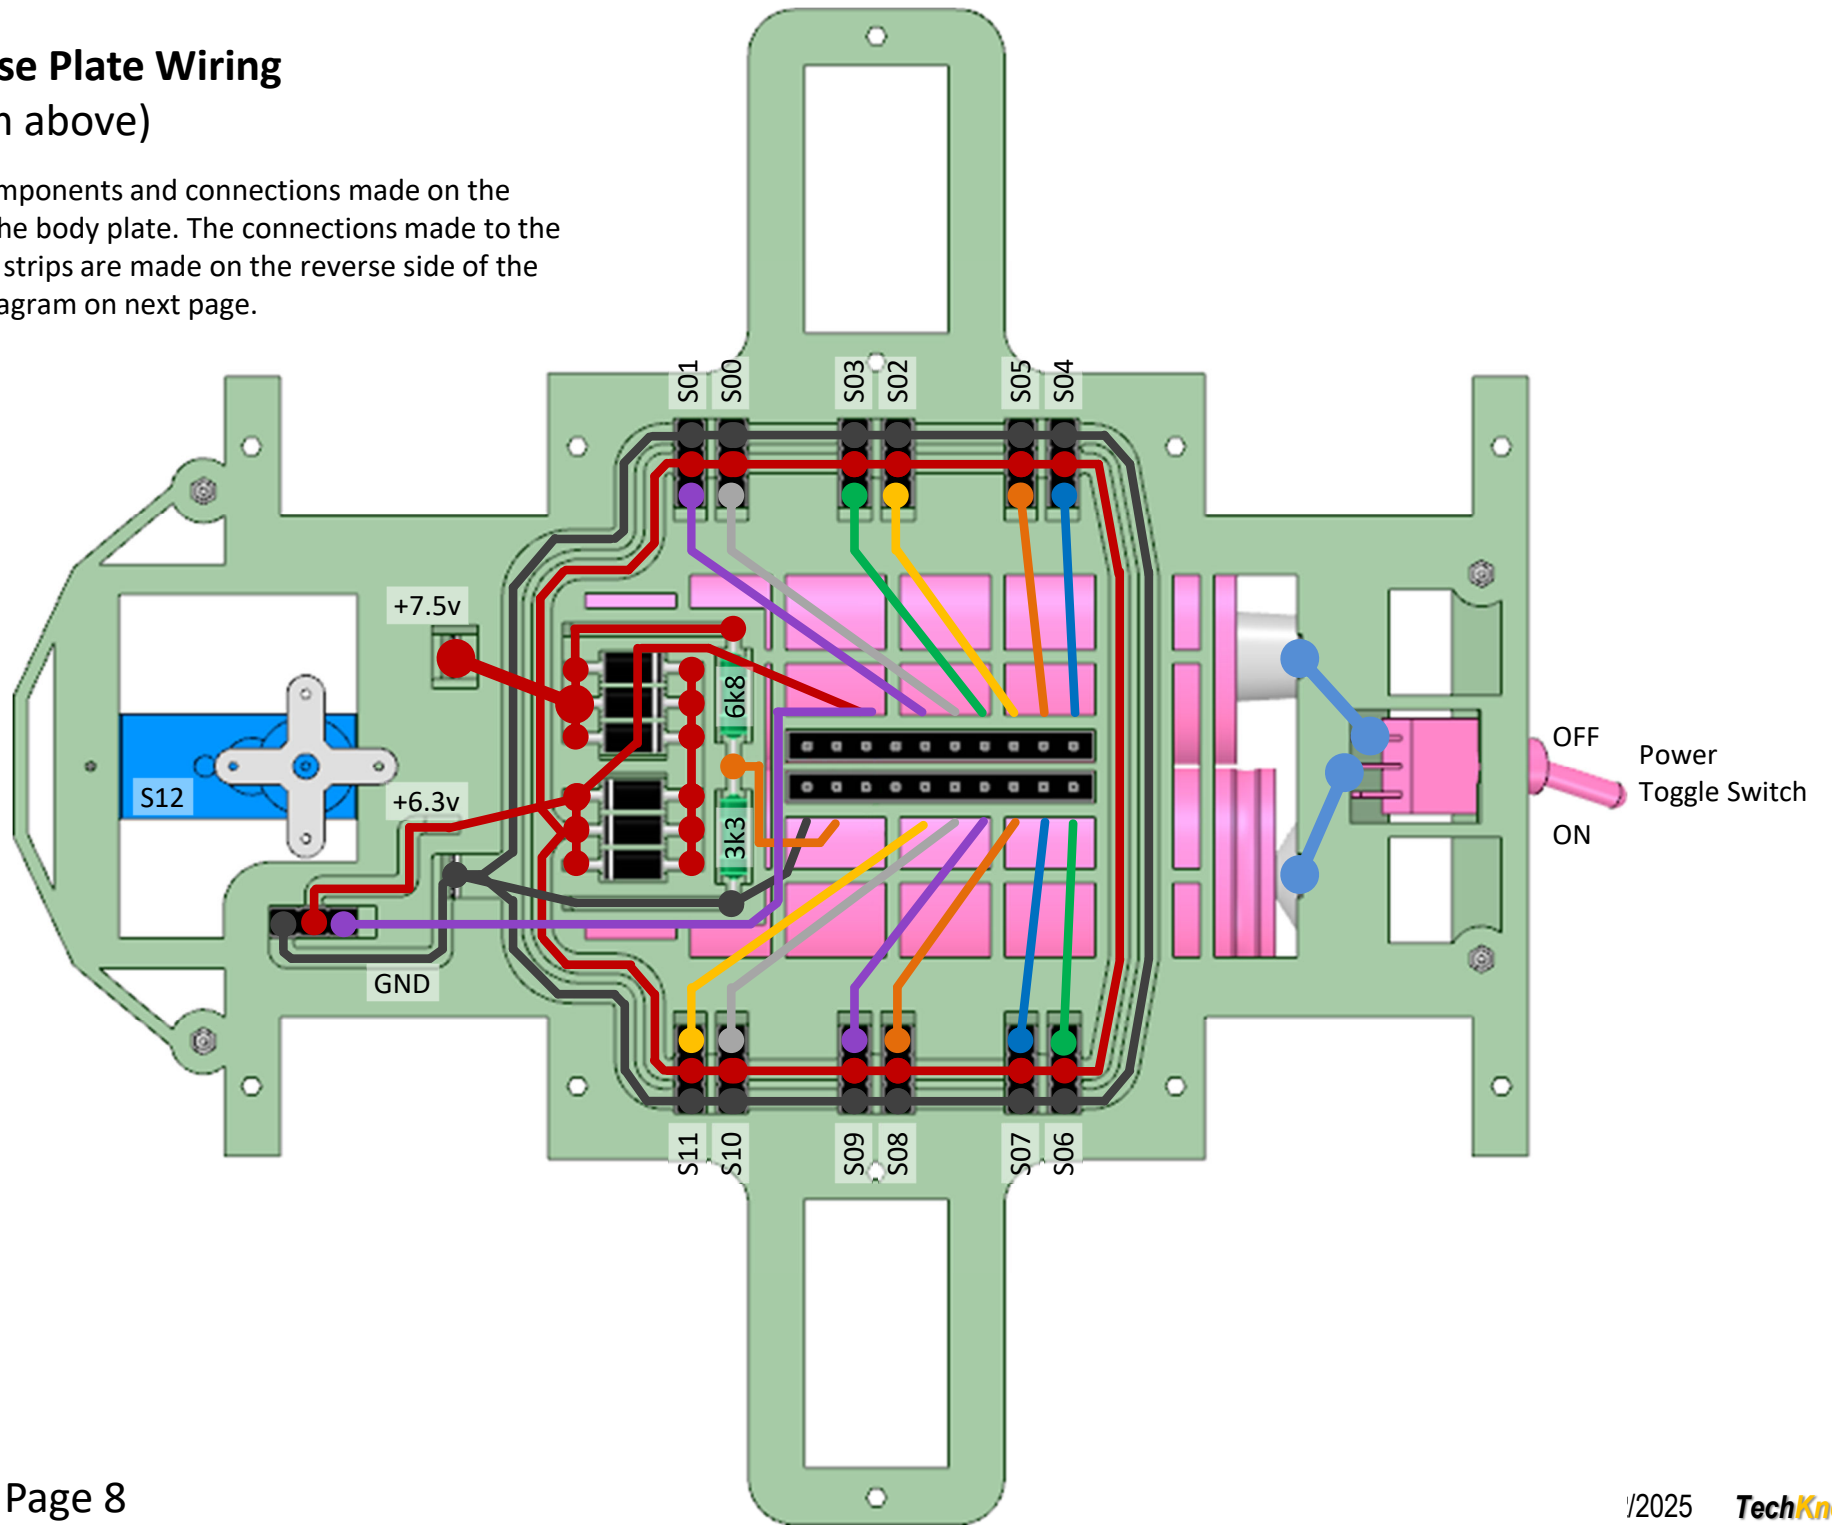

HexdBot 2 Control Wiring

A pin and socket solution is used to connect the microcontroller on the micro plate to the power and servo connections on the body plate. This schematic shows the connections to the two 10 pin connectors.

HexBot 2 Base Plate Wiring (viewed from above)

This shows the components and connections made on the upper surface of the body plate. The connections made to the two 10-pin socket strips are made on the reverse side of the body plate. See diagram on next page.

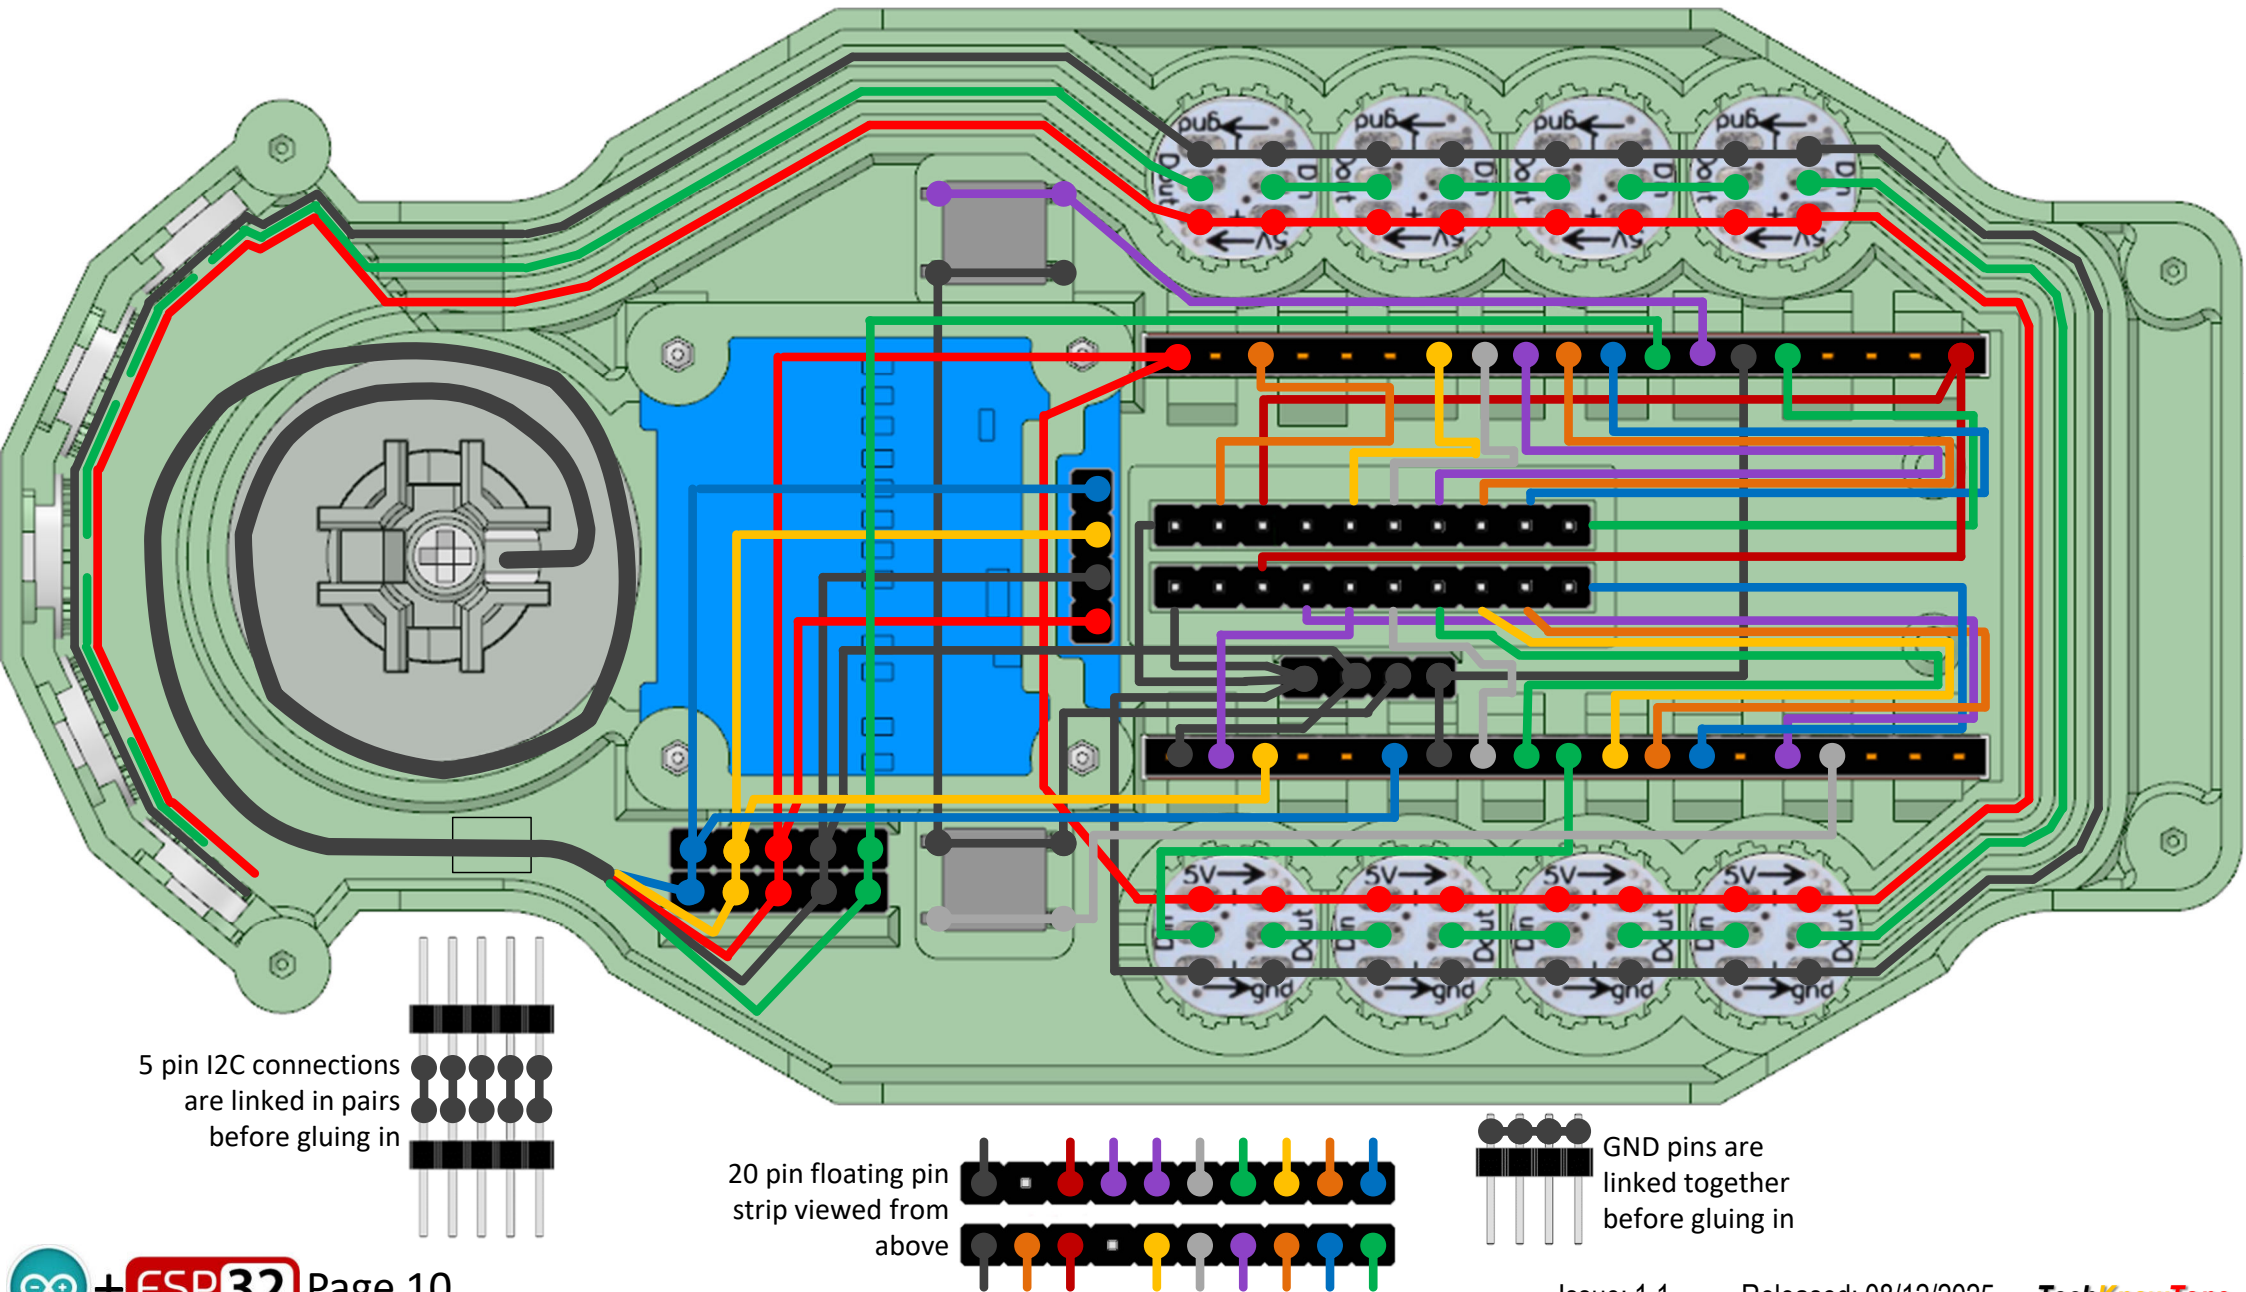

HexBot 2 Base Plate Wiring (viewed from below)

This shows the connections made to the two 10-pin socket strips. The wires are fed through to the upper surface of the body plate, shown in the previous diagram.

HexBot 2 Micro Plate Wiring (viewed from below)

Note that the wiring for the centre floating 20 pin connector are longer than shown in some cases, and all are looped back towards the rear of the robot. This gives the floating connector scope for movement, and makes it much easier to insert this pin connector into the base plate sockets during final assembly. See photos to follow.

Wiring Sequence

01 Start with the body plate

02 Once removed they should look like this:

03 Refer to the 3D Parts document

04 Remove the outside pins of 5-pin strips

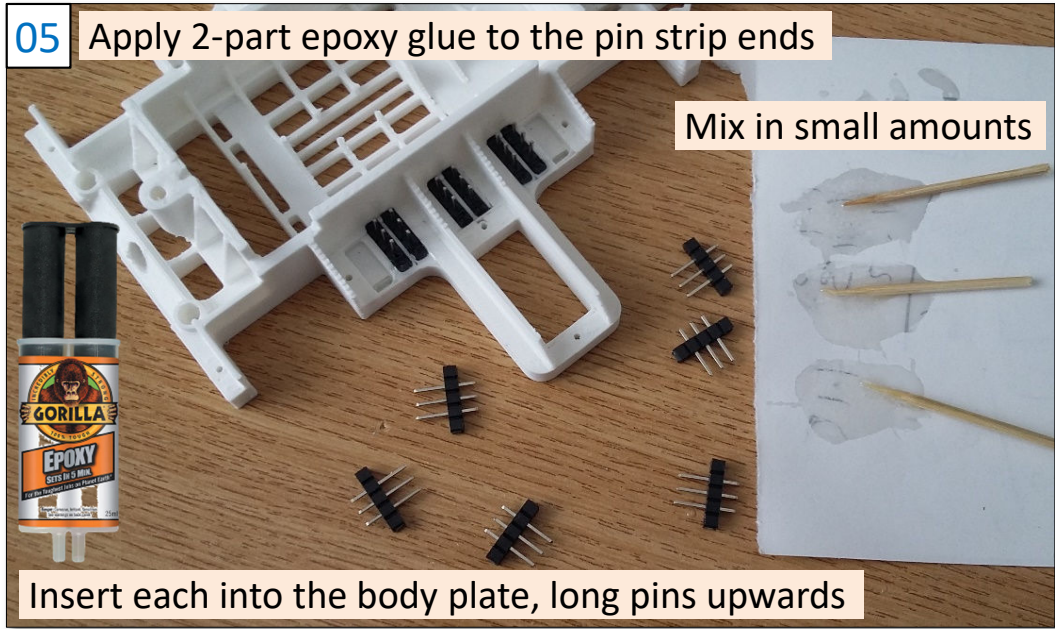

Wiring Sequence

05 Apply 2-part epoxy glue to the pin strip ends

Mix in small amounts

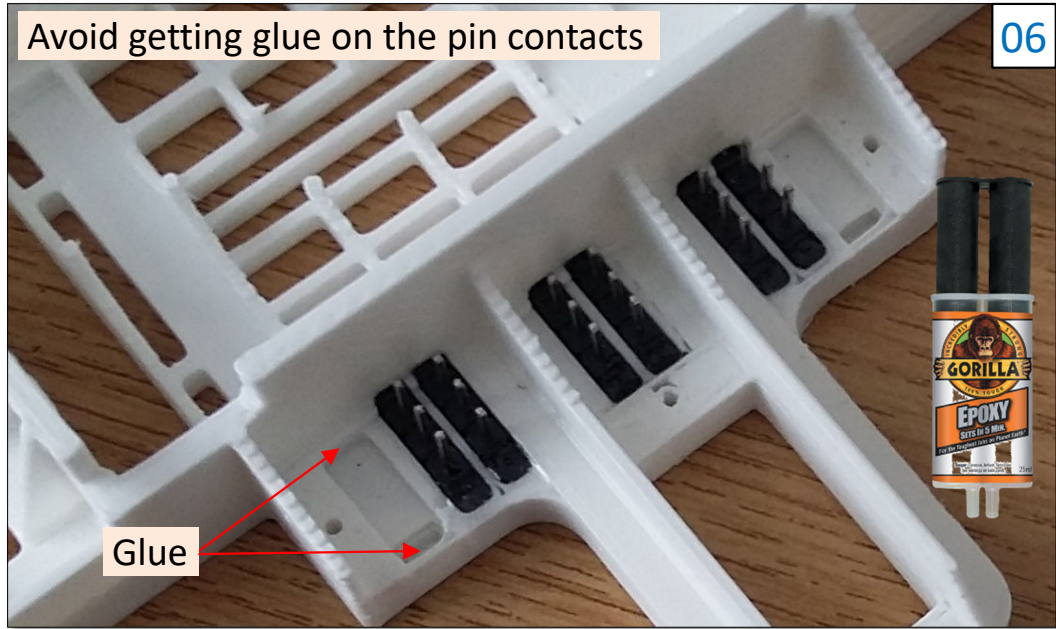

Insert each into the body plate, long pins upwards

A top-down view of a white plastic body plate on a wooden surface. A tube of Gorilla Epoxy is on the left. Several black pin strips are scattered on a white paper in the center, with wooden toothpicks used for mixing the epoxy. The body plate has several rectangular slots for the pin strips.

Avoid getting glue on the pin contacts

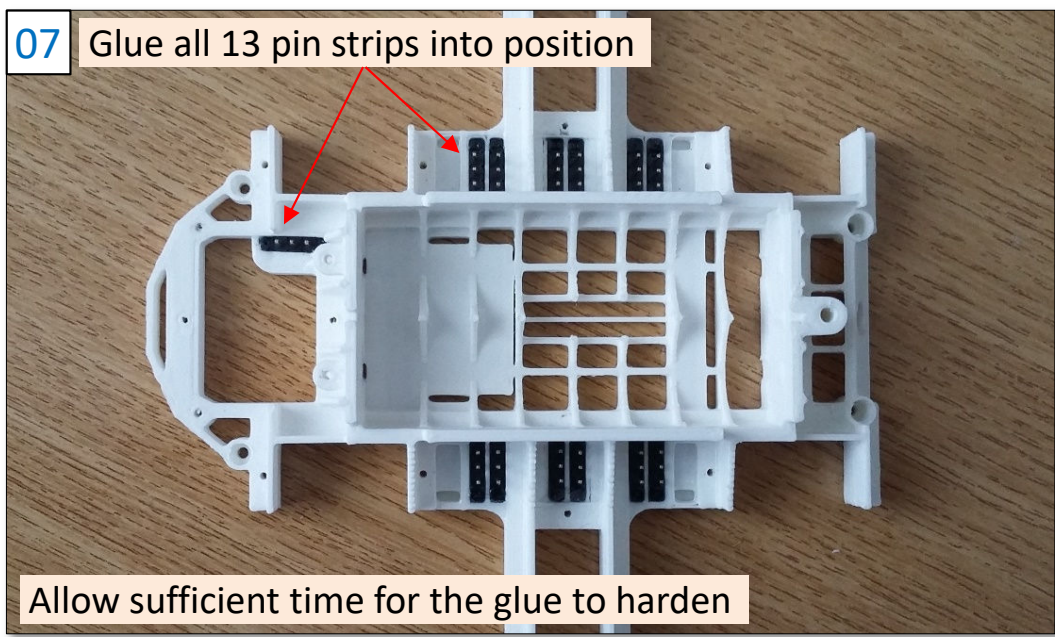

Glue

06

A close-up view of the body plate's pin slots. Red arrows point to the gaps between the slots, with the word 'Glue' in a box. A tube of Gorilla Epoxy is on the right. The pin strips are already partially inserted into the slots.

07 Glue all 13 pin strips into position

Allow sufficient time for the glue to harden

A top-down view of the white plastic body plate with all 13 black pin strips inserted into their respective slots. Red arrows point to the strips. The assembly is on a wooden surface.

Insert the 13 RGB LEDs into the micro plate

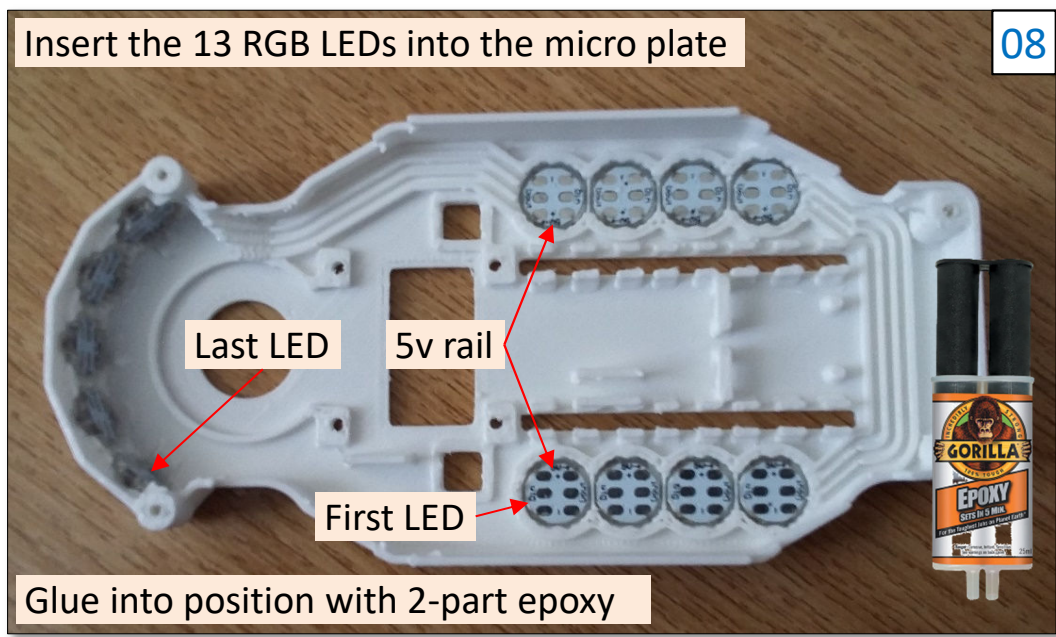

Last LED

5v rail

First LED

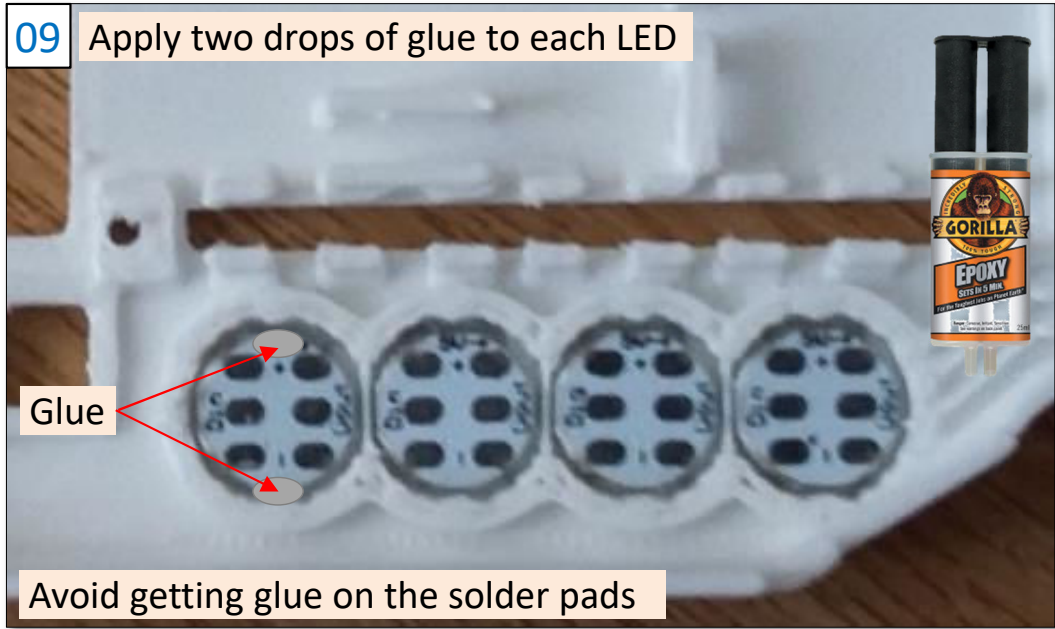

Glue into position with 2-part epoxy

08

A top-down view of the white plastic micro plate. It has two rows of four circular LED footprints each. Red arrows point to the 'Last LED' and 'First LED' positions, and a '5v rail' is also labeled. A tube of Gorilla Epoxy is on the right. The plate is on a wooden surface.

Wiring Sequence

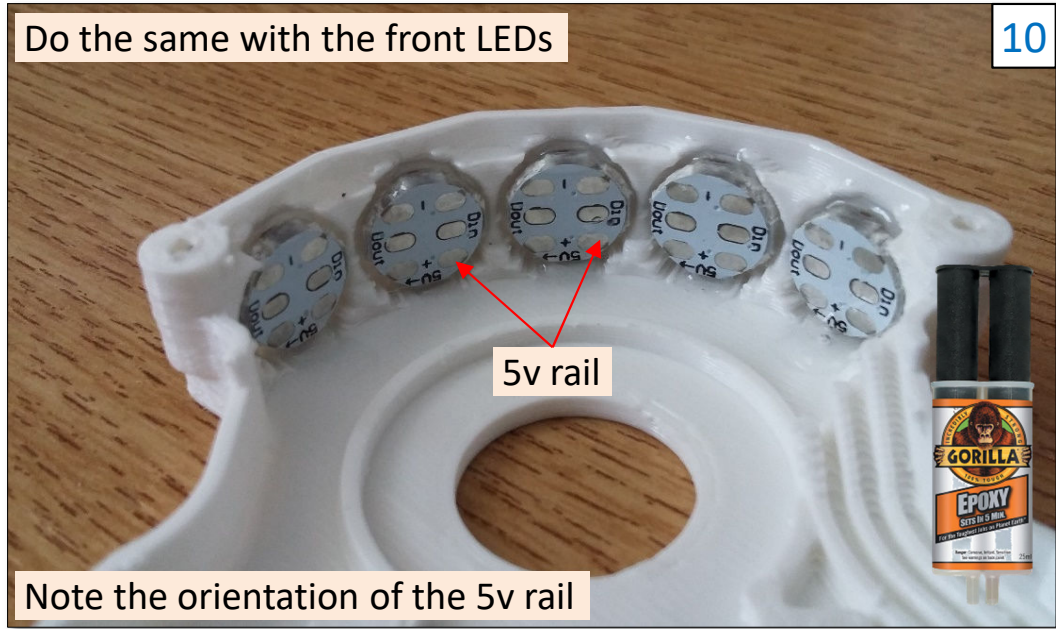

09 Apply two drops of glue to each LED

Glue

Avoid getting glue on the solder pads

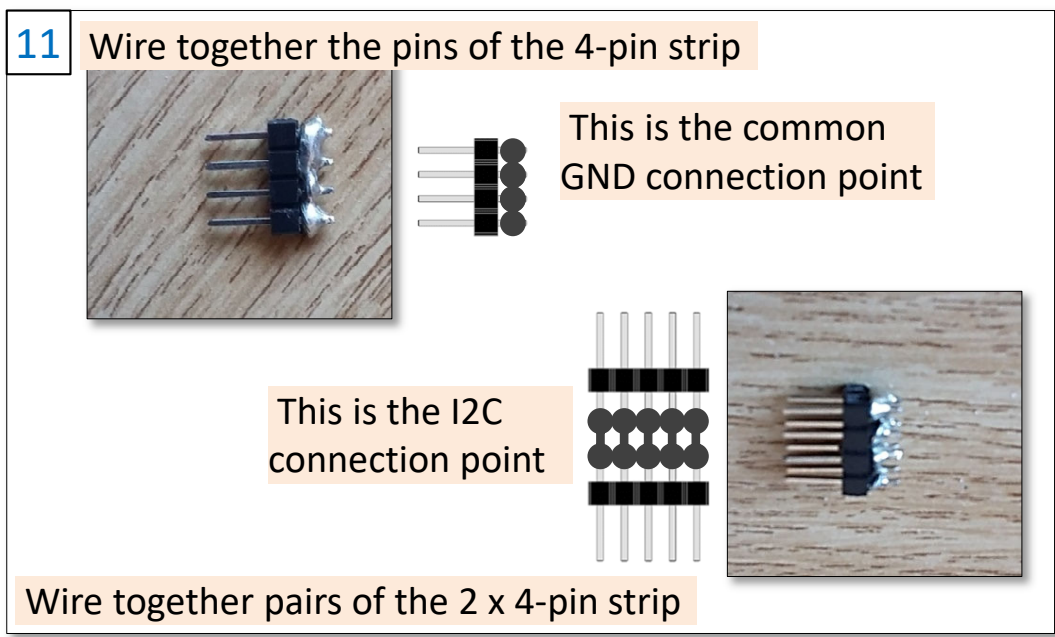

Do the same with the front LEDs

5v rail

Note the orientation of the 5v rail

11 Wire together the pins of the 4-pin strip

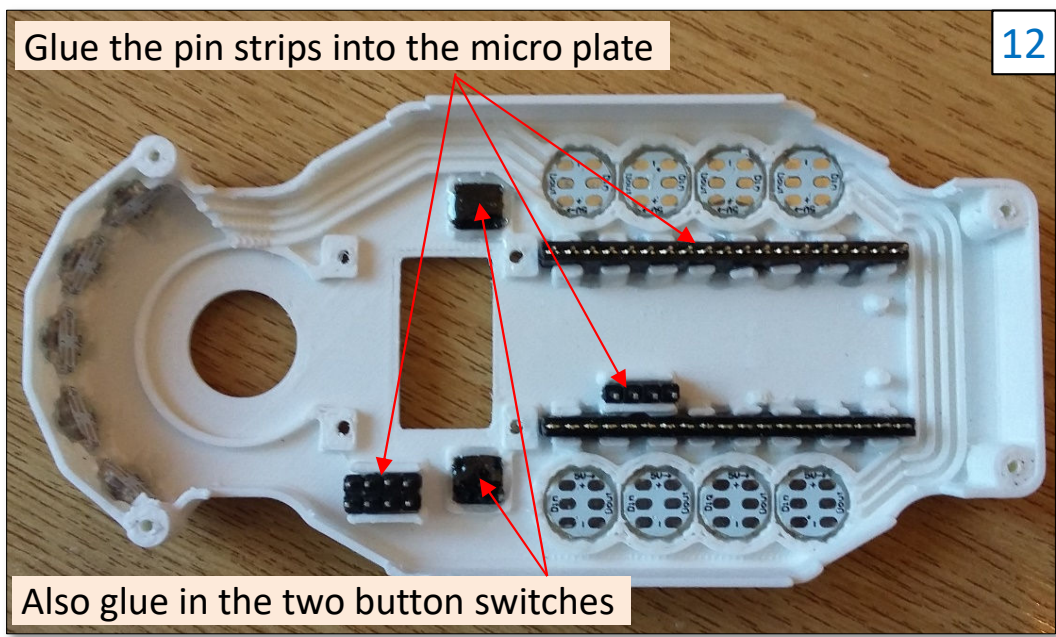

This is the common GND connection point

This is the I2C connection point

Wire together pairs of the 2 x 4-pin strip

Glue the pin strips into the micro plate

Also glue in the two button switches

Wiring Sequence

13 Trial fit the battery connections

Ensure you have the correct polarity

14 Glue these into position, one at a time

Allow time for the glue to stiffen, before doing the next

15 Now glue in the 6 x 1N4006 diodes

Ensure you have the correct polarity

16 Mount the display in the micro plate

Use the display strap and 4 screws

Wiring Sequence

17 Glue in the two resistors

18 Strip wire and tin and solder in as tracks as show

19 Now solder in power wires

20 You can now test the LEDs on the top plate

Wiring Sequence

21 Now wire wrap the display I2C interface

Next wire wrap the push two button switches

22

23 Use tinned wire to form a servo power bus loop

Wire up the control harness described overleaf

24

HexBot 2 Micro Plate Harness Wiring (viewed from above)

Note: start with 14cm lengths of wire minimum. Make the connections to the two pin strips first; then apply heat shrink sleeving to group the wires together as shown; first as two harnesses then grouped together as one near the pin strip end. Finally wire the free ends to the ESP32 socket strip connectors, as shown in the previous image.

Note: The top pin strip has two purple wires and the lower strip has two orange wires. Make one of the wires longer in each case, or tie a small knot at the end, so that you can identify them when they are bundled together.

Note: Plugging the 20 pin floating pin strips into the sockets on the body plate will help to hold the job whilst you apply the wire wrap wire, and the heat shrink sleeving

Wiring Sequence

25 Position the harness as show within the top plate

Note that the pins are pointing upwards

26 Wire wrap one side of the harness

27

The wire wrap the other side

28 The joints can be soldered after testing

28

HexBot 2 Head Wiring

Note: start with 22cm lengths of wire minimum. Make the connections to the pins on the VL53L1X sensor first. Then feed the five wires through the neck aperture before screwing on the eye plate. Then mount the head onto the top face of the micro plate and glue the retaining disc into position from the other side, with the wiring protruding through the neck aperture.

Turn the head 90° to the left, then coil the wires around the neck in an anti-clockwise direction for 1½ turns, as shown below. Then make off the wire wraps to the 4 pin I2C strip. Check that the head can be rotated from left to right without the wire coiling too tightly on the neck. The glue the wire to the vertical supporting post as a tether point.

Wiring Sequence

29 Your top plate wiring should now look like this

30

Wire wrap one side of the base plate connector

31

Then wire wrap the other side of the base plate connector

32

Carefully bring the top plate onto the base plate

Plug in the pin strip connector as you do so

Wiring Sequence

33 Dress the base face of the servos with a file, to ensure...

...they are flat and to roughen them slightly.

34 Glue a bearing plate onto the bottom of each servo.

Clamp in position whilst the glue sets.

35 Avoid getting glue in the bearing hole

If this does happen, remove the glue before it hardens!

36 Cut the servo leads with sufficient length to make-off...

..new crimp connections.

Wiring Sequence

37 Mount the front and rear servo motors before...

38 Then mount the side servo motors.

39 Next mount the head servo motor.

40 Then fit the chin cover.

Wiring Sequence

41 Mount the front and rear servo motors before...

42 Glue the servo arms into the lever plates

43 Attach the lever and link plates to the servos

44 Viewed from below

Wiring Sequence

45

Now attach the claw servos

Loop the servo wires so they can move freely

46

47

Glue the battery clip onto the battery cover

48

The fitted cover looks like this

Wiring Sequence

49

50

RGB LED assignments

Battery Voltage Health Monitoring

See 18650 discharge curve obtained from the internet. In this analysis both batteries are identical and connected in series, Assume fully charged batteries max voltage is $V_{BM} \geq 8.2v$ max I measured my rechargeable PP3 at 8.65v when connected and ON. Set battery warning point at $V_B = 7.00v$ Set battery critical point at $V_{BC} = 6.60v$

ESP32 is powered from batteries connected to V_{in} . 3.3v at $V_{ADC} == 4095$ on 12-bit converter (4095 max). If we use a 6k8 resistor feeding A0 and a 3k3 resistor to GND, we get a conversion factor of $10.1v == 4095$ or 2.47mV/bit or 404.85 Using a Multimeter I determined the conversion factor needed to be reduced to 383.9 to display voltage correctly.

18650 Lithium Battery Discharge Profile

Discharge: 3.0V cutoff at room temperature.

MAX: $V_M = 8.2v$, gives $A0 = 3148$ on ADC ($V_M * 383.9$)

WARNING: $V_B = 7.0v$, gives $A0 = 2687$ on ADC ($V_B * 383.9$)

CRITICAL: $V_{BC} = 6.6v$, gives $A0 = 2534$ on ADC ($V_{BC} * 383.9$)

The code will sample the battery voltage on power-up to ensure it is sufficient, then at every 40ms interval, calculating an average (1/20) to remove noise.

Given the relatively light current drawn I have assumed a linear discharge curve ranging from 8.2v (100%) to 6.6v (0%) capacity. The rate of discharge is monitored and used to actively predict the life of the battery in use.

Note: If connected to USB port with internal battery switched OFF the ADC will read a value 5 volts ($A0 = 1919$) or less. So if the micro starts with such a low reading it knows that it is on USB power.
